

POWER BI VISUALISATION DOCUMENTATION

TOPIC: Analysis of Netflix Movie Trends

Data Analytics / Entertainment Industry Analysis (Netflix Movies & Shows Analysis)

Objective

1. To analyze the Netflix dataset and explore trends in movies and TV shows.
2. To identify the most popular genres, languages, and content categories.
3. To study the relationship between ratings, popularity, and audience engagement.
4. To create meaningful visualizations that help understand viewing patterns and content performance.

Summary of Findings

The Netflix movie dataset contains information about movie popularity, audience ratings, vote counts, genres, languages, and release years.

The analysis shows that movie popularity is unevenly distributed, with only a small number of movies becoming highly popular while most movies receive moderate popularity. Audience engagement, measured by vote count, generally increases with popularity, indicating that well-known movies attract more viewers and interactions.

Genre analysis reveals that certain genres consistently perform better in terms of popularity and ratings. Similarly, some original languages dominate the dataset, suggesting that Netflix has a stronger content library in those languages.

The correlation analysis indicates a positive relationship between popularity and vote count, meaning movies that are more popular usually receive more audience votes. However, popularity does not always guarantee higher ratings, showing that marketing success and audience satisfaction are not always the same.

Overall, the dataset provides valuable insights into audience preferences and content performance.

Key Insights

Insight 1

Movies with higher popularity generally receive significantly more audience votes, indicating strong viewer engagement.

Insight 2

Certain genres consistently achieve higher average popularity and ratings than others, making them valuable content categories.

Insight 3

English-language movies dominate the dataset, while movies in several regional languages represent opportunities for market expansion.

Insight 4

Only a small percentage of movies become blockbuster titles, as shown by the popularity and vote count outliers.

Insight 5

Audience ratings remain relatively stable across most movies, suggesting that popularity is influenced by multiple factors beyond movie quality, such as marketing and audience reach.

Business Recommendations

Recommendation 1

Invest more resources in high-performing genres that consistently attract larger audiences.

Recommendation 2

Increase production and acquisition of content in emerging regional languages to expand the subscriber base.

Recommendation 3

Promote highly rated but less popular movies through personalized recommendations to increase viewer engagement.

Recommendation 4

Use popularity and vote count together when recommending movies instead of relying only on ratings.

Recommendation 5

Analyze blockbuster movies separately to identify characteristics that contribute to exceptional success and replicate those strategies in future productions.

Final Story with the Dashboard

The dashboard tells the complete story of how Netflix movies perform from multiple perspectives.

The analysis begins by examining the overall movie collection through genre and language distributions. It then explores how audiences interact with movies by analyzing popularity, vote counts, and ratings.

The scatter plots demonstrate that highly popular movies generally attract more audience votes, indicating strong engagement. However, not every popular movie receives the highest ratings, suggesting that audience satisfaction depends on both content quality and promotional efforts.

The grouped analysis and heatmaps reveal which genre-language combinations perform best, enabling better content planning. The bubble plot highlights blockbuster movies that combine high popularity, excellent ratings, and large vote counts.

Overall, the dashboard provides decision-makers with a comprehensive understanding of audience preferences, movie performance, and market trends. These insights can support data-driven decisions related to content production, acquisition, recommendation systems, and international expansion.

Netflix Movies Data Analysis Dashboard

Conclusion

The Netflix Movies Analysis demonstrates how Python and Power BI can transform raw movie data into meaningful business insights. Through data cleaning, visualization, and statistical analysis, the project identifies audience preferences, content trends, and performance patterns. The interactive dashboard enables stakeholders to monitor key metrics efficiently and supports data-driven decisions for content production, recommendation systems, and strategic business planning. Overall, this project highlights the value of data analytics in improving decision-making within the entertainment and streaming industry.
